# Der $\beta$ -Zerfall

# Der $\beta$ -Zerfall

I have done a terrible thing, I have  
postulated  
a particle that cannot be detected.

# Das Neutrino

- Elektrisch ungeladen und fast masselos

- Masse:

- “Geisterhaft”, nimmt nur an schwacher WW teil  
( $10^{-11}$  Wahrscheinlichkeit beim Flug durch die Erde @ 1 MeV)
- Durch euch fliegen etwa  $5 \cdot 10^{14}$  Sonnenneutrinos pro Sekunde

# Die vollständige(?) Standardmodell

PHYSICS

● Quarks

● Leptonen

● Kraftteilchen

● Higgs

# Photon-Astronomie

ERLANGEN CENTRE  
FOR ASTROPARTICLE  
PHYSICS

# Was hat das mit Teilchenphysik zu tun?

- Alle stabilen Teilchen können Boten sein

# Höhenstrahlung

ERLANGEN CENTRE  
FOR ASTROPARTICLE  
PHYSICS

- Radioaktivität nimmt (entgegen der Erwartung) mit der Höhe zu  
→ die Erde muss von geladenen Teilchen getroffen werden

# Luftschauer

- Primärteilchen interagiert hoch in der Atmosphäre und bildet Schauerfront
- Sekundärteilchen zerfallen (teilweise) auf dem Weg zum Boden

# Energiespektrum

ERLANGEN CENTRE  
FOR ASTROPARTICLE  
PHYSICS

## Cosmic Ray Spectra of Various Experiments

SCIENCE TIP: LOG SCALES ARE FOR QUITTERS WHO CAN'T FIND ENOUGH PAPER TO MAKE THEIR POINT PROPERLY.

Energy (eV)

# Energiespektrum

ERLANGEN CENTRE  
FOR ASTROPARTICLE  
PHYSICS

Cosmic Ray Spectra of Various Experiments

- Doppellogarithmisch Achsen
- (Eine Größenordnung pro Strich)
- Anzahl  $\sim E^{-2,x}$
- Substrukturen geben Aufschluss über veränderte Herkunft

# Richtung

ERLANGEN CENTRE  
FOR ASTROPARTICLE  
PHYSICS

Die geladenen Teilchen werden in intergalaktischen Magnetfelden abgelenkt und zeigen nicht mehr auf ihren Ursprung

→ trotz Jahrzehnten an Forschung kennen wir die Quellen der kosmischen Strahlung kaum

ERLANGEN CENTRE  
FOR ASTROPARTICLE  
PHYSICS

# Neutrino-Astronomie

- Neutrinos entstehen zusammen mit den geladenen kosmischen Teilchen, gehen nicht verloren und werden nicht abgelenkt  
→ ideale Botenteilchen

# Neutrino - Quellen

- Sonne ( $7 \cdot 10^{10}$  pro  $\text{cm}^2$  und Sekunde)  
~5000 pro Jahr gemessen
- SN1987a (Sternexplosion)  
24 Neutrinos gemessen

**Detektor  $\sim 0,00003 \text{ km}^3$**

# Herausforderung 1

- Nur wenige Ereignisse pro  $\text{km}^2$  und Jahr erwartet  
→ riesige Detektoren nötig

# Herausforderung 1

- Nur wenige Ereignisse pro km<sup>2</sup> und Jahr erwartet  
→ riesige Detektoren nötig

# Herausforderung 2

- Neutrinos entstehen auch in den Luftschauern geladener Teilchen, die wollen wir nicht sehen

Wir haben 2013 die ersten extrasolaren Neutrinos gefunden (wie siehe nächsten Vortrag), aber die Himmelskarte füllt sich nur langsam.
