

Fermi + HESS analysis on the Crab nebula

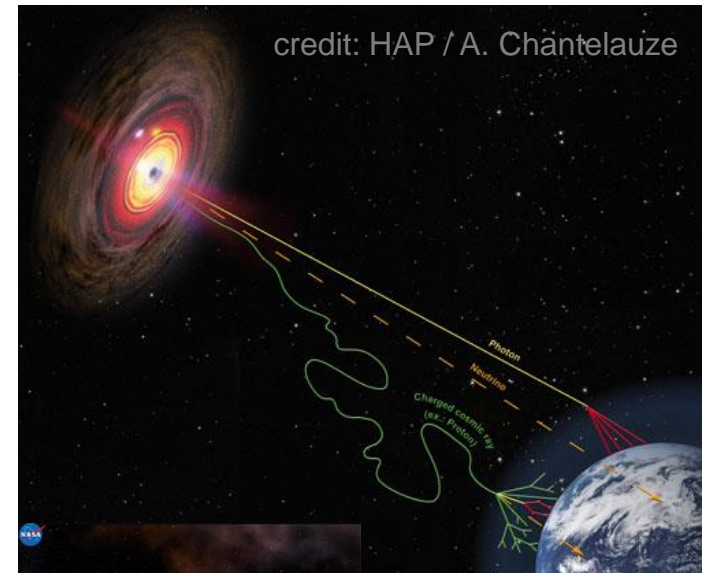

Tim Unbehaun – Synergies in Non-Thermal Astrophysics in Southern Africa
Erlangen, 30.07.2024

Motivation

- Crab nebula as bright, well studied gamma-ray source
- Test a joint-likelihood analysis where the data of the two instruments is combined at the event level
- Use Fermi-LAT + H.E.S.S. data to constrain the Inverse Compton spectrum and morphology of the nebula
- Combine with radio to x-ray data of the synchrotron regime
- Compare to the prediction of phenomenological Synchrotron-Self-Compton models
- Publication at <https://arxiv.org/abs/2403.12608>

Credit: HESS Collaboration

3D analyses with Gammapy

Gammapy is an open-source Python package for gamma-ray astronomy built on Numpy and Astropy. It is a prototype for the Cherenkov Telescope Array (CTA) science tools, and can also be used to analyse data from existing gamma-ray telescopes.

- Binned likelihood analysis in 3D (2 spatial, 1 energy)
- Combination of different data sets at likelihood level
→ can fit same physical model to data from different instruments
- Requirement: instrument data (DL3) in common format
→ can also include i.e neutrino data,
although package is designed for γ -ray data analysis

- MapDataset holds counts, IRFs (exposure, PSF, energy dispersion) background-model, source models
 - *Counts* cube with two spatial axes + one energy axis
 - *Npred* cube with model prediction (forward folded with IRFs)
- Likelihood fitting:
 - Poisson probability in pixel i to measure n counts given the model prediction $v(\xi)$ for parameters ξ

$$P(n_i | v_i(\xi)) = \frac{v_i(\xi)^{n_i}}{n_i!} \times \exp(-v_i(\xi))$$

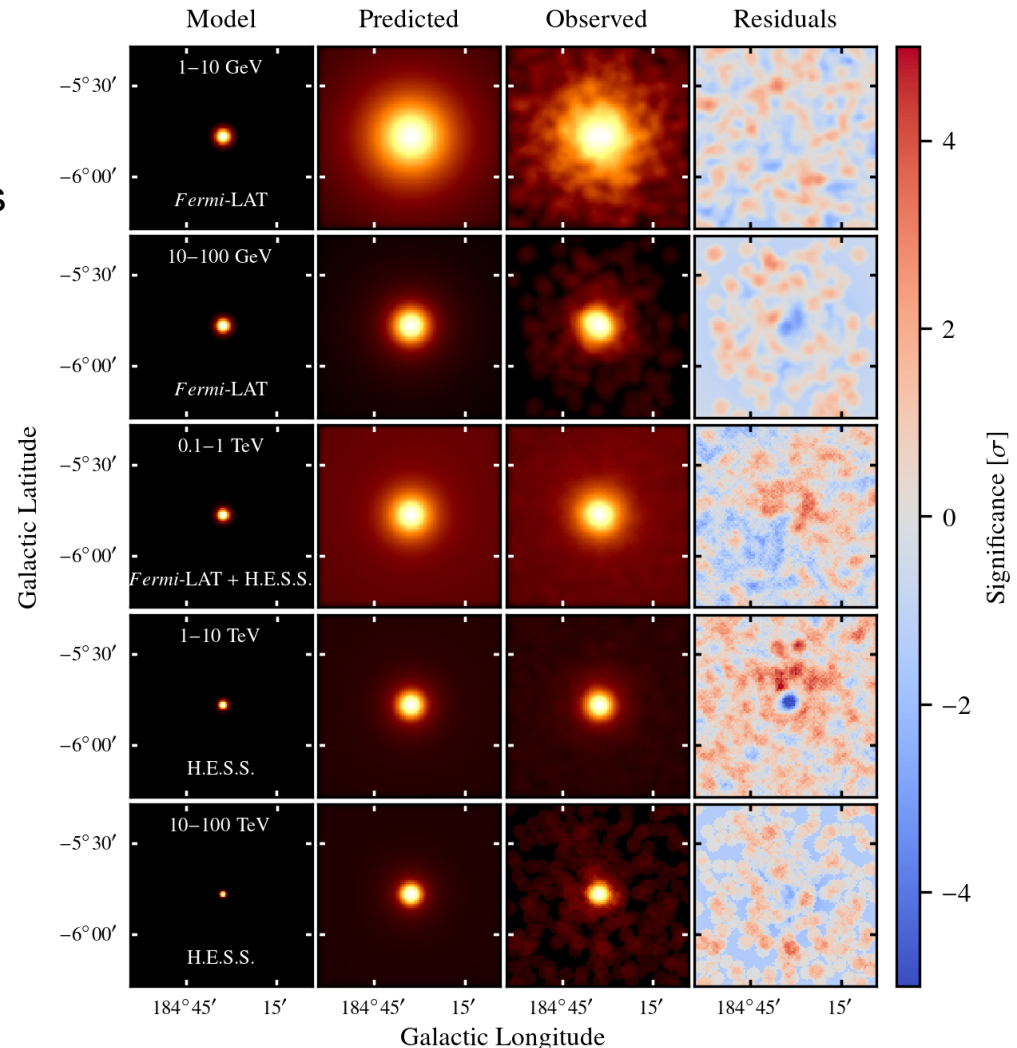

- LogLikelihood:

$$-\ln \mathcal{L}(\xi) = - \sum_{i=1}^N \ln \left[\frac{v_i(\xi)^{n_i}}{n_i!} \times \exp(-v_i(\xi)) \right]$$

- Minimizing $TS \equiv -2 \ln \mathcal{L}$ maximizes the Likelihood

Fermi + HESS on the Crab

- Models predict flux as function of spatial and energy coordinates
- Forward folding of the model prediction using the respective IRFs of each instrument
- Minimizing the combined likelihood with respect to the binned counts

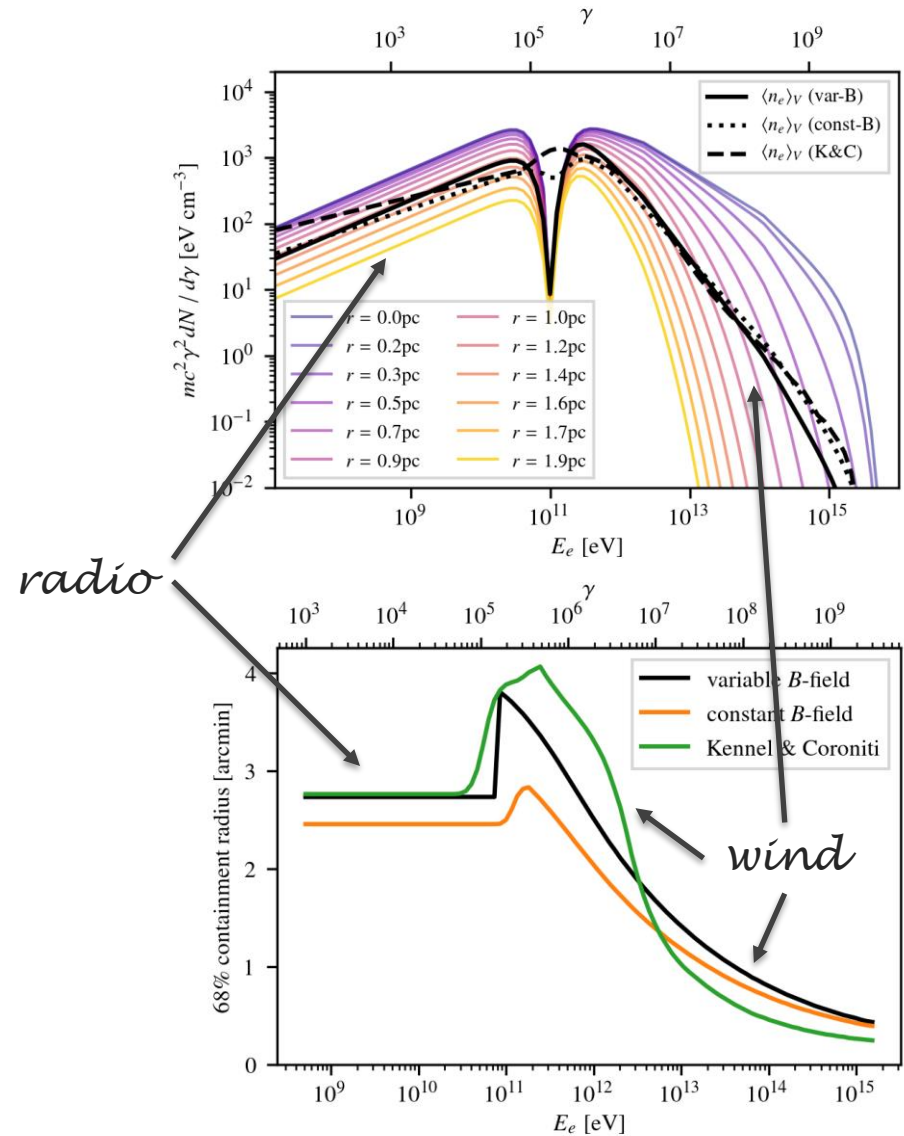

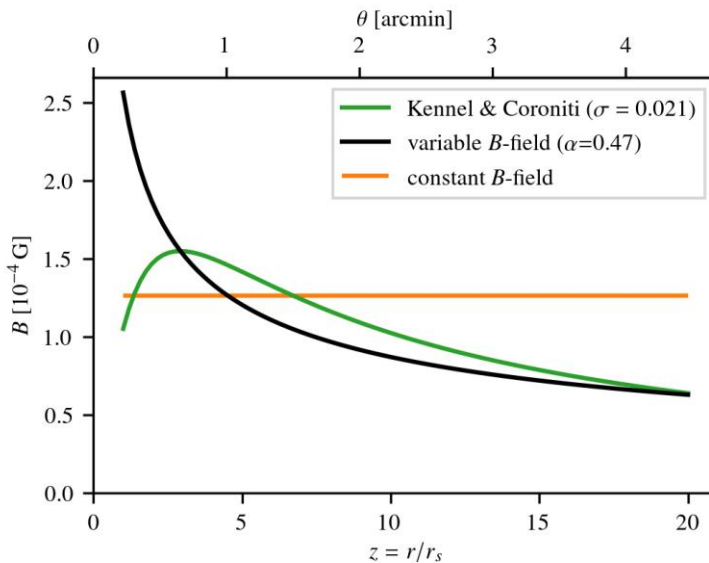

The spectrum

The models

- Parametrized distribution of relic ‘radio’ electrons (low energy, constant extension) and injected ‘wind’ electrons (high energy, decreasing extension)
- The models mostly differ by the assumed B-field profile

The spectrum

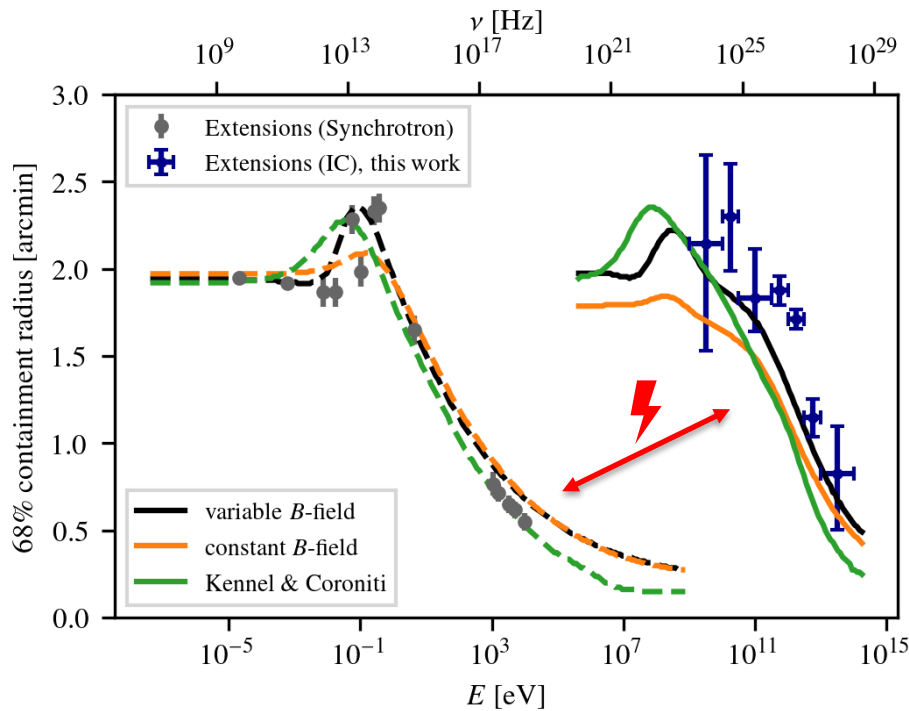

The spectrum

The extension

- The models underpredict the hard x-ray flux while overpredicting the highest energy gamma-ray flux (same electrons responsible for both)
- The small x-ray extension seems to be in conflict with the larger IC extension of the nebula if both are indeed produced by the same electrons

Thanks for your attention!
